COLOR CHANGING CORRECTION FLUID

BACKGROUND

Cross References to Related Application

5 This application claims the benefit under 35 U.S.C. § 119(e) of U.S. provisional patent application Serial No. 60/508,095 filed October 2, 2003, the disclosure of which is incorporated herein by reference.

Technical Field

10 Improved correction fluid compositions are disclosed. More specifically, correction fluid compositions are disposed which change color upon drying to indicate to the user when the correction fluid has sufficiently dried and therefore can be written or printed upon.

Background of the Related Art

15 Correction fluids are used for correcting handwritten, typewritten, photocopied and printed markings on paper, cardboard and other surfaces. Generally, such correction fluids are applied to the surface in a liquid form and then subsequently allowed to dry to form a film which covers the incorrect markings on the surface. After drying, the coating of correction fluid can then be written upon to form the corrected marking.

20 Important characteristics for any correction fluid is the ability to provide a film or coalesced residue on the surface which can both effectively cover the incorrect marking and provide an effective service for receiving the correcting marking. The film covering the marking should be strongly bonded to the paper or substrate surface but also should be sufficiently flexible so that the film will not be 25 removed or cracked during normal handling of the paper. Additionally, the correction fluid should not interact with the corrected marking which would result in discoloration of the resulting film or a "bleed through" of the incorrect marking through the correction fluid layer.

30 Another important characteristic of any correction fluid is the drying rate of the fluid. Specifically, the drying rate should be as rapid as possible so that the correction can be made relatively quickly. Typical correction fluids having a drying time ranging from 30 to 40 seconds depending upon the thickness of the coating applied. Other desired performance characteristics include good storage ability, good

flow and viscosity characteristics and the ability of the fluid to be mixed quickly and/or remain in a suspension for long periods of time.

5 Early correction fluids included organic solvents but in recent times water-based correction fluids have been utilized because they are better for the environment. Typically water-based correction fluids include a pigment, *e.g.*, titanium dioxide, and a film forming polymer, such as latex.

10 One problem associated with current water-based correction fluids is the inability for the consumer to determine when the correction fluid has sufficiently dried so as to enable the consumer to write over it. Currently, the consumer is forced to employ a trial and error technique. If the consumer does not wait a sufficient amount of time, *e.g.*, greater than 30 seconds, the consumer's pen will penetrate the partially-dried film resulting in the incorrect marking being partially uncovered as well as an unsmooth surface. Then, the consumer must reapply another coat of correction fluid and wait all over again.

15 One solution to this problem is disclosed in Japanese Patent No. JP 6049397 which discloses a correction fluid formulation that includes water, a volatile organic solvent such as ethanol or acetone and a pH color changing indicator. The formulation relies upon the reaction with carbon dioxide in air that results in a pH change (the mixture becomes less basic or more acidic) to provide the lowering of the 20 pH resulting in the color change of the pH color changing indicator. However, two different solvents are required, water and a polar organic solvent, and the reliance upon the interaction of the mixture with carbon dioxide for producing the color change is slow and unreliable.

25 Therefore, there is a need for an improved correction fluid formulation which provides a reliable visual indication to the user when the correction fluid is sufficiently dry and ready to receive written or printed corrections.

SUMMARY OF THE DISCLOSURE

30 In satisfaction of the aforesaid needs, an improved correction fluid is disclosed which changes color upon drying to provide the user with a reliable indication that the correction fluid is sufficiently dry and ready to receive corrected markings in the form of writing or printing. In an embodiment, an improved color changing correction fluid comprises water as the sole solvent, either a volatile base or

a volatile acid, and a color changing pH indicator. Preferably, the color changing correction fluid does not include substantial amounts of organic solvents of either a polar or non-polar nature.

In a refinement, a volatile base is employed and is selected from the group 5 consisting of tri-ethylamine (TEA), 2-amino-2-methyl-1-propanol (AMP), dimethylaminopropylamine (DMAPA), N,N-dimethylethanolamine (DMEA), ammonia and mixtures thereof.

In another refinement, a volatile acid is used which comprises acetic acid and/or another volatile acid such as formic acid and mixtures of volatile acids.

10 In another refinement, the color changing pH indicator is selected from the group consisting of pentamethoxy red, methyl red, methyl yellow, phenolphthalein, thymophthalein, p-naphtholbenzein, 4-nitrophenol, 3-nitrophenol, o-cresolphthalein, m-cresol red, thymol blue, m-cresol purple and mixtures thereof.

15 In another refinement, the color changing correction fluid further comprises a film-forming polymer. In a further refinement, the film-forming polymers are stable at a high pH of about 13 down to a low pH of about 4, has a solids level ranging from about 35% to about 65% and a glass transition temperature (T_g) ranging from about -35 to about 100°C.

20 In a further refinement, the film-forming polymer is selected from the group consisting styrene acrylic latexes, acrylic latexes, vinyl acetate ethylene latexes and mixtures thereof. Further, a coalescent aid can be used to enhance the film-forming process although some polymers disclosed herein can form films without coalescent aids. If a coalescent aid is utilized, plasticizers are preferred and can be selected from the group consisting of dipropylene glycol dibenzoate, isodecyl benzoate, 25 ditridecylphthalate, and mixtures thereof.

In a further refinement, titanium dioxide is a preferred pigment and can constitute from about 20 to about 60 wt% of the fluid mixture. Additional extender pigments can be utilized such as aluminum silicate, calcium carbonate, magnesium silicate, calcium silicate, potassium aluminum silicate and mixtures thereof.

30 The viscosity of the resulting correction fluid at 25°C is preferably between 5 and 20,000 cps. However, this range can be extended, depending on the particular applicator utilized, *i.e.*, a brush or stylus. For example, the viscosity at 25°C could range from about 10 to about 800 cps for brush or foam applicators, from about 5 to

about 100 cps for correction markers and from about 20 to about 20,000 cps for pens that require the correction fluid to be squeezed through a stylus from a flexible reservoir. The solids level in the preferred color changing correction fluids range from about 45 to about 75% by weight, and more preferably from about 55 to about 5 70% by weight.

Additional additives such as biocides, defoamers, surface tension modifiers, pigment dispersants, surfactants, anti-settling agents, freeze-thaw stabilizers, thickeners and other additives can be utilized that are known to those skilled in the art.

10

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

An improved color changing correction fluid made in accordance with this disclosure includes water as the primary solvent, thereby avoiding the need for organic solvents and the environmental concerns associated therewith, a volatile base 15 or acid and a color changing pH indicator. Preferred volatile bases include diethylenetriamine (DETA), dimethylaminopropylamine (DMAPA), methoxypropylamine (MPA), triethylamine (TEA), 2-amino-2-methyl-1-propanol (AMP), N,N-dimethylethanolamine (DMEA), ammonia and mixtures thereof. If a volatile acid is utilized, a preferred volatile base is acetic acid because of its relative 20 volatility, low cost, environmental friendliness and lack of unpleasant odors associated therewith.

Preferably, the volatile base or acid constitutes from about 0.1 to about 10 wt% of the fluid mixture. Further, a mixture of different amines can be 25 advantageous. For example, the combination of ammonia which is a quickly evaporating amine with DMEA, which is slowly evaporating amine, can be effective. Further, a combination of TEA as a quickly evaporating amine with AMP as a slowly evaporating amine can be utilized.

Preferred color changing pH indicators include pentamethoxy red, methyl red, methyl yellow, phenolphthalein, thymophthalein, p-naphtholbenzein, 4-30 nitrophenol, 3-nitrophenol, o-cresolphthalein, m-cresol red, thymol blue, m-cresol purple and mixtures thereof.

The correction fluid should also include a film-forming polymer and possibly a film-forming aid or coalescent aid. Suitable film-forming polymers are

stable at a pH of up to about 13 and a pH of down to about 4, have a solid level from about 35% to about 65% in a glass transition temperature (T_g) ranging from about -35 to about 100°C. Suitable film-forming polymers include Pliotech™ 7822 or 7217 (acrylic latexes sold by Eliokem), Joncroyo™ 537, 617, 1907, 2561, 2646 or 2660 5 (acrylic latexes sold by Johnson Polymers), Jonrez™ 2051, 2080, 2008 or 2005 (styreneacrylic latexes sold by Westvaco), Durvace™ FT-3020 (vinyl acetate ethylenes latex sold by Reichhold), Ucar™ latexes (sold by Don Chemical) and other latexes meeting conditions aforementioned. Suitable coalescent aids include Benzoflex™ 9-88 (dipropylene glycol dibenzoate sold by Velsicol Chemical Corp.) 10 Velate™ 262 and 368 (isodecyl benzoate, also sold by Velsicol Chemical Corp), Texanol™ (ester alcohol sold by Eastman Chemical), Jayflex™ (ditridecyl phthalate sold Exxon Mobil Chemical).

The preferred pigment is titanium dioxide in an amount ranging from about 20 to about 60 wt%, preferably from about 35 to about 50 wt%. Suitable 15 titanium dioxide pigments include Ti-Pure™ R-931, 902, 706 (sold by DuPont), Tioide™ R-XL, TR90 (sold by Huntsman), Kronos™ 2131 (sold by Kronos), and Tipaque™ R-930, R-980 (sold by Ishihara) and many other titanium dioxide pigments meeting conditions aforesaid. An extender pigment may also be utilized and suitable extender pigments include, but are not limited to aluminum silicate, calcium 20 carbonate, magnesium silicate, calcium silicate, potassium aluminum silicate and mixtures thereof.

Formulation of the color changing correction fluid will be best illustrated by the following examples.

Example 1

25 137.5 g Kronos 2131 titanium dioxide pigments was dispersed in 55g water and proper amount of pigment dispersants and defoamers. Then under mixing, 40g of Pliotec 7822 latex, 2g TXIB coalescent, 2g AMP-95 and 2g DMAPA, 0.6 g phenolphthalein pH indicator and other additives were added. The resulting fluid can be applied to paper for correction by either brush and/or foam applicator.

Example 2

In 60 g water with pigment dispersant and defoamer, 137.5g TiPure R-902 titanium dioxide was added and dispersed. Then 25.4g Joncrys 2646 and 6.7g Joncrys 537 latex, 4g DMAPA, 0.6g o-cresolphthalein and other additives were 5 mixed. The fluid was applied by either brush and/or foam applicator for correction.

The fluids prepared as set forth above were subjected to both room temperature and accelerated aging experiments. Both fluids showed good stability.

While only certain embodiments have been set forth, alternative embodiments and various modifications will be apparent from the above description 10 to those skilled in the art. These and other alternatives are considered equivalents within the spirit and scope of this disclosure.
